VDR

## ABSTRACT

The effects of vitamin D are mediated through the vitamin D receptor (VDR), a predominantly nuclear receptor, expressed in numerous tissues including the placenta. VDR and the retinoid X receptor (RXR) form a dimer complex which binds to genomic vitamin D responsive elements located primarily in promoter regions and recruit cell-specific transcription factor complexes which regulate the expression of numerous genes. To investigate the role of VDR on regulating placental gene expression, mice heterozygous (+/−) for an ablated *Vdr* allele (C57Bl6 strain B6.129S4-VDRtm1Mbd/J, Jackson Laboratory) were mated to generate *Vdr*<sup>+/+</sup>, *Vdr*<sup>+/-</sup> and *Vdr*<sup>-/-</sup> fetuses and placental samples were collected at day 18.5 of pregnancy. RNA was isolated from placental tissue with global gene expression measured using Affymetrix Mouse Gene 2.1 ST Arrays to assess the effects of VDR on global gene expression in the placenta. All raw array data are deposited in Gene Expression Omnibus (GEO) under accession [GSE61583](https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE61583).

## Specifications

Organism/cell line/tissue	Global <i>Vdr</i> ablated C57Bl6 (strain B6.129S4-VDRtm1Mbd/J, Jackson Laboratory JAX Mice Services) mouse placenta tissue collected at day 18.5 of pregnancy.
Sex	Male and female
Sequencer or array type	Affymetrix Mouse Gene 2.1 ST Array
Data format	Raw CEL files
Experimental factors	3 genotype groups, <i>Vdr</i> knockout (−/−), <i>Vdr</i> heterozygous (+/−) and wild-type (+/+).
Experimental features	<i>Vdr</i> heterozygous males and females were mated to generate <i>Vdr</i> knockout, heterozygous and wild-type offspring. At day 18.5 of pregnancy, mouse placentas were collected and RNA was extracted and assayed on Affymetrix MoGene 2.1 ST arrays to measure the effect of <i>Vdr</i> on global gene expression.
Consent	Data is publicly available and open for re-use given appropriate citation.
Sample source location	Adelaide, Australia

## 2. Experimental design, materials and methods

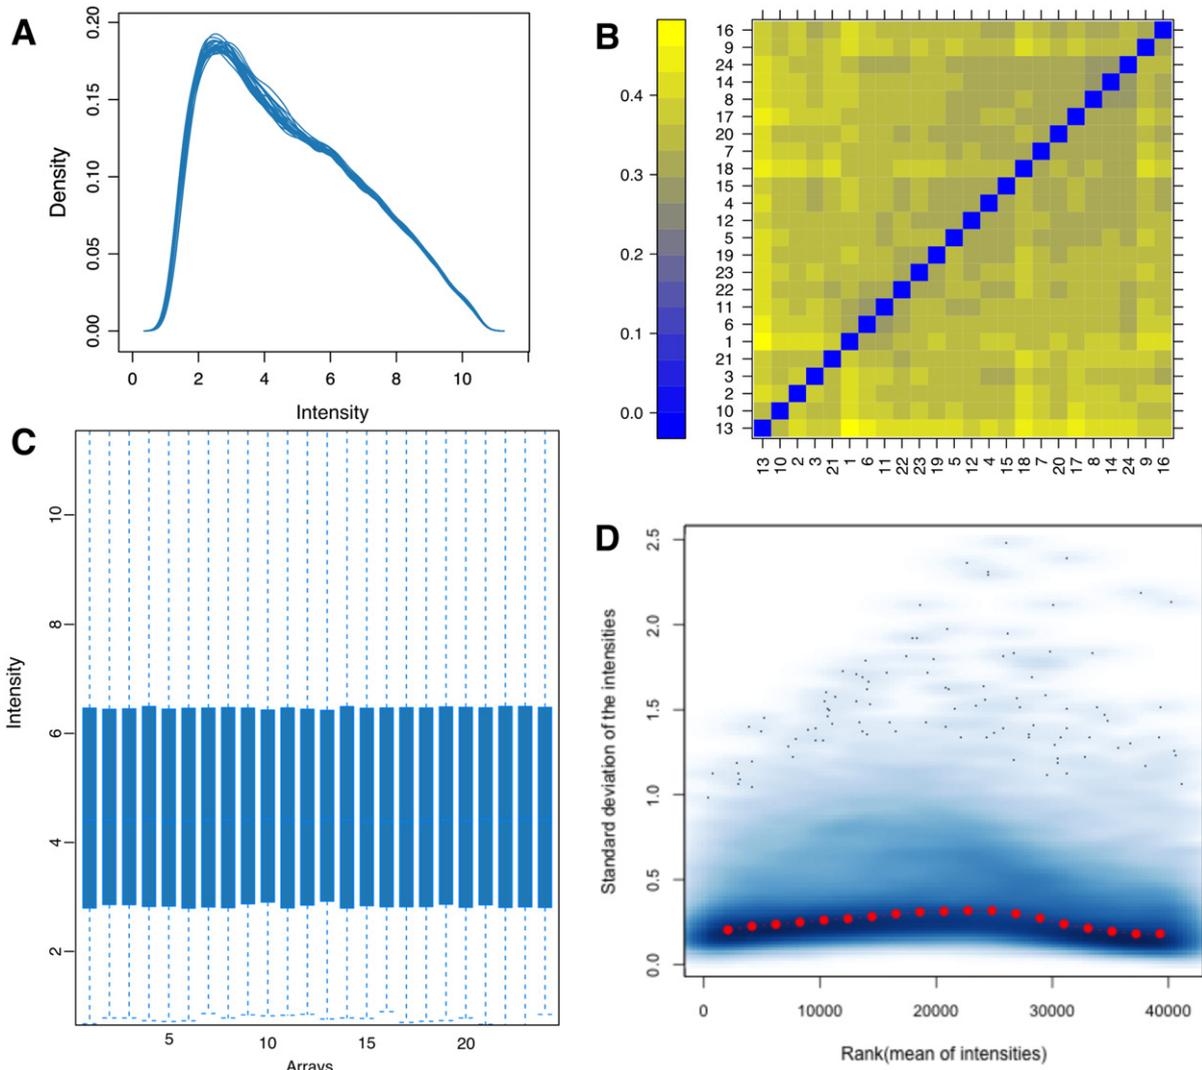

Male and female mice heterozygous for the *Vdr* allele (*Vdr* knockout strain B6.129S4-Vdrtm1Mbd/J – The Jackson Laboratory) were mated at 10–12 weeks of age to generate offspring of the three genotype combinations: *Vdr* knockout, *Vdr* heterozygotes and Wild-type. Twelve *Vdr*<sup>+/-</sup> females were mated at 10–12 weeks of age with *Vdr*<sup>+/-</sup> males. At day 18.5, females were euthanised and placental tissue was collected and bisected mid-sagittally with half stored in RNAlater and at −80 °C. All mice were raised on a standard chow diet.

To isolate RNA, placental tissue was homogenised using a Powerlyzer with ceramic 1.4 mm beads before extraction using TRIzol (Invitrogen) following the manufacturer's instructions. To determine fetal *Vdr* genotypes and sex, DNA was extracted from fetal tails and genotyped by PCR as described in reference [1].

Biotinylated cRNA was prepared according to the standard Affymetrix protocol from 250 ng total RNA following the Manual Target Preparation Guidelines for GeneChip® Whole Transcript (WT) Expression Arrays. 3.5 µg of fragmented and labeled single-stranded cRNA was

hybridized on Affymetrix MoGene 2.1 ST arrays and washed and stained following the Manual Target Preparation Guidelines for GeneChip® Whole Transcript (WT) Expression Arrays. Arrays were scanned using the Affymetrix GeneChip scanner by the Ramaciotti Centre for Genomics, Sydney, Australia.

Microarray quality control was carried out on the raw un-normalised using the ArrayQualityMetrics R package [2], which showed that there were no significant outlier samples and the data appeared to be of good quality (Fig. 1).

The results of this study, along with detailed experimental design and discussion are presented in reference [1]. This work was supported

by a National Health and Medical Research Council Project grant awarded to CTR and PHA (GNT1020754).
