# 1 A scoping review of Australian evaluations of health care delivery 2 models: are we making the most of the evidence?

## 3 Abstract

### 4 *Objective*

5 Health care delivery models describe the organisation of health care practitioners and other  
6 resources to provide health care for a defined patient population. The organisation of health  
7 care has a predominant influence on the receipt of timely and appropriate health care. Efforts  
8 to improve health care delivery should be evidence-informed and large numbers of evaluations  
9 of health care delivery models are undertaken. This paper presents a scoping review of  
10 Australian evaluations of new health care delivery models, to inform a discussion of the  
11 appropriate use of such evidence to improve the efficiency and sustainability of the Australian  
12 health system.

### 13 *Methods*

14 A systematic scoping review was undertaken, following an a priori published protocol.  
15 PubMed, Embase and CINAHL were searched for primary, comparative studies of health care  
16 delivery models undertaken in Australia and published between 2009 and 2018. Primary  
17 prevention studies, such as health promotion activities, were excluded.

### 18 *Results*

19 Of 14,923 citations, 636 studies were included. 383 (60%) randomised controlled trials were  
20 identified. There were 18 clinical specialties in which over 10 evaluations were identified. Most  
21 models involved allied health practitioners or nurses.

## 22 *Conclusion*

23 Evaluations of health care delivery models provide important evidence that can be used to  
24 improve the use of health systems' most important and costly assets – the health care  
25 practitioners who deliver health care. A nationally co-ordinated system is required to support  
26 local health services to assess the local value of alternative health care delivery models.

27

## 28 **Key Question Summary**

### 29 *1. What is known about the topic?*

30 The organisation and delivery of health care is continuously evolving in response to changes  
31 in the demand and supply of health care. New health care delivery models are often evaluated  
32 in specific locations, but it is not clear how such evidence informs the delivery of care in  
33 other locations.

### 34 *2. What does this paper add?*

35 This paper reports the findings of a scoping review of Australian evaluations of health care  
36 delivery models, highlighting the large and increasing number of such evaluations that have  
37 been published in the last ten years.

### 38 *3. What are the implications for practitioners?*

39 Opportunities to improve health system efficiency are likely being lost due to the underuse of  
40 the available Australian evidence on new health care delivery models. Local health services  
41 need support to interpret such evidence in their local context, which could be provided through  
42 the development of a national framework for **local evaluation**.

43

## 44 Introduction

45 Health care delivery models describe the organisation of health care practitioners and other  
46 resources to provide health care for defined patient populations. Such models represent the  
47 systems within which health care is delivered, which are the principal determinants of whether  
48 patients receive timely and appropriate health care. Improving systems is difficult,<sup>1</sup> but it is an  
49 ongoing and necessary focus of all health systems. Evidence is an important input to  
50 improvement processes and evaluations of new health care delivery models are undertaken  
51 across the Australian health system, funded by the National Health and Medical Research  
52 Council, governments, local health services and charities.<sup>2</sup>

53 However, the lack of a consistent and co-ordinated approach to the use of evidence on health  
54 care delivery models undervalues the available evidence and is likely to result in missed  
55 opportunities to improve the Australian health system. Decisions to fund and implement new  
56 health care delivery models are made by state and territory health departments, Local Hospital  
57 Networks and Primary Health Networks, as well as by private health care providers. Some  
58 institutions have defined processes for designing models of care as part of a commissioning  
59 cycle,<sup>3-5</sup> but a more co-ordinated approach to the implementation of evidence-based health  
60 care delivery models has the potential to significantly improve the efficiency and sustainability  
61 of the Australian health system.

62 The aim of this scoping review is to profile the volume and coverage of existing evaluations of  
63 health service delivery models undertaken in Australia, and to discuss why it might be  
64 underused and options for using this evidence to improve the Australian health system.

## 65 **Methods**

66 A scoping review was undertaken according to a published *a priori* protocol [REF]. The review  
67 was conducted and reported in line with the Joanna Briggs Institute (JBI) Reviewers' Manual  
68 and the PRISMA Extension for Scoping Review checklist.<sup>6,7</sup>

### 69 *Eligibility criteria*

70 Only primary studies undertaken solely in Australia were included in the review. Studies were  
71 required to evaluate a health care delivery model that provided a new service, or delivered an  
72 existing service using an alternative set or mix of health care practitioners. Evaluated health  
73 care delivery models could be compared to a current practice health care delivery model or to  
74 no treatment. All population groups with an existing health condition were included. Primary  
75 prevention studies, such as health promotion activities, were excluded.

### 76 *Search strategy*

77 Searches were conducted in the following databases for citations published in English:  
78 PubMed, Embase and the Cumulative Index to Nursing and Allied Health Literature  
79 (CINAHL). Papers published between 1 January 2009 and 31 December 2018 were included.  
80 The final search strategy for PubMed is available in the Supplementary File.

### 81 *Study selection*

82 Due to the large number of citations identified, the title and abstract review was undertaken in  
83 two steps. One reviewer screened all titles, with a second reviewer screening 10% of titles to  
84 ensure agreement. All abstracts were then screened by two reviewers. Screening and selection  
85 of full-text articles was done by one reviewer, with 10% checked by a second reviewer. The  
86 PRISMA diagram can be found in the Supplementary File.

87 *Methodological quality appraisal*

88 Methodological quality assessment and risk of bias were not undertaken for this study,  
89 consistent with scoping review guidance.<sup>6</sup>

90 *Data extraction*

91 An extraction form developed using Microsoft Excel (2013) was used to extract data. The first  
92 10% of data extraction was done by two reviewers. The remaining data extraction was  
93 completed by one reviewer. Free text descriptions of the clinical area, evaluated health care  
94 delivery model, workforce effects and sample size were extracted. In addition, fixed categories  
95 were defined to standardise study characteristics with respect to geographical setting  
96 (metro/regional/rural), clinical areas (as per the Medical Board of Australia),<sup>8</sup> health system  
97 setting (primary and community care/outpatient/emergency care/inpatient/aged care),  
98 workforce (allied health/nursing/GP/specialist/non-clinical) and study type (RCT/cohort/pre-  
99 post with control/pre-post without control).

100 *Synthesis of results*

101 Descriptive statistics are used to summarise the characteristics of the included studies using the  
102 fixed category variables, presenting the numbers of studies in different categories. Two-way  
103 analyses are also presented, e.g., reporting the numbers of studies by health system setting and  
104 workforce categories. To illustrate the range and potential value of the reported evidence,  
105 included studies in the clinical area ‘Emergency medicine’ published in the last six months of  
106 2018 were reviewed in more detail. The NHMRC’s framework<sup>9, 10</sup> for assessing the quality of  
107 scientific evidence was applied to the selected Emergency Medicine studies to illustrate the  
108 relevance and reliability of the evidence, as well as the magnitude of the potential benefits  
109 associated with the implementation of new health care delivery models.

## 110 Results

111 The review included 636 studies, of which 108 (17%) were published in Australian journals.  
112 521 (74%) were undertaken in metropolitan areas, 68 (10%) and 71(10%) were undertaken in  
113 regional and rural areas, respectively. The most common study design was a randomised  
114 controlled trial (383, 60%), with similar numbers of pre-post studies without controls (124,  
115 19%) and cohort studies (124, 19%). Victoria (158, 25%), New South Wales (142, 22%) and  
116 Queensland (136, 21%) accounted for almost 70% of all studies. Very few studies were  
117 undertaken in Tasmania, the Northern Territory and the ACT. There were 37 (6%) national  
118 studies and 46 (7%) multi-state studies.

119 Figure 1 presents the studies categorised by clinical specialty, noting studies can be assigned  
120 to multiple specialties, e.g., an evaluation of rehabilitation after hip surgery is categorised as  
121 both rehabilitation medicine and orthopaedic surgery. There were 18 clinical specialties with  
122 more than 10 evaluations, and four specialties in which there were 70 or more evaluations  
123 (psychiatry, cardiology, geriatric medicine, and rehabilitation medicine).

124 Figure 2 presents the number of included evaluations by health system setting and workforce  
125 category. Accounting for studies undertaken across multiple settings, there were over 200  
126 evaluations in each of primary and community, outpatient and inpatient settings. Almost 70%  
127 of these evaluations involved the provision of health care by allied health practitioners or  
128 nurses, who were also involved in more than half of the evaluations undertaken in the  
129 emergency department and aged care settings.

130 Using the NHMRC's framework for assessing the quality of scientific evidence,<sup>9, 10</sup> Table 1  
131 presents summaries of four evaluations published in the last six months of 2018 in the clinical  
132 area of Emergency Medicine (ED).

133 The health care delivery models piloted were diverse and their implementation requires  
134 resource re-allocation. The only RCT, of a facilitated intervention to increase uptake of  
135 guidelines for minor traumatic head injury, reported increased aggregate costs and no  
136 significant difference in clinical outcomes.<sup>11</sup> The pre-post evaluation of a nurse-led  
137 intervention to improve the care of frail older people in the ED reported reduced ED and  
138 inpatient costs and reduced hospital admission rates, though it was not clear if intervention  
139 costs were included. The lower 95% confidence interval for hospital re-presentations was 0.99,  
140 implying uncertainty regarding the non-inferiority of the intervention.<sup>12</sup>

141 The retrospective cohort analysis of direct versus indirect transport to a PCI-enabled hospital  
142 was limited by the extent to which available data included all potential confounders.<sup>13</sup> It is  
143 possible that the data did not capture in full the factors influencing paramedics' decisions  
144 regarding initial destination hospital. However, the study reported a very large intervention  
145 effect, risk differences of over 10% for surviving to hospital discharge, 30 days and 12 months.  
146 The pre-post evaluation of a behavioural assessment unit in the ED was unable to control for  
147 other changes in the ED over the timeframe of the study but it did report significant reductions  
148 in ED length of stay and in 'actual or potential violent, aggressive, abusive or threatening  
149 behaviour' (defined as Code Greys).<sup>14</sup>

## 150 Discussion

151 The implementation of new health care delivery models requires the re-allocation of resources,  
152 typically involving either the substitution of one type of health care practitioner with another  
153 or the employment of a new set of health care practitioners. Decisions are required to make  
154 such re-allocations. The aim of the presented scoping review is to highlight the large number  
155 of health care delivery models that have been evaluated in Australia, in order to promote  
156 consideration of a more systematic approach to the use of this evidence base to inform decisions

157 to fund and implement health care delivery models. The review identified 636 published  
158 Australian evaluations in the last ten years, with an increasing trend in the number of  
159 publications each year. The evaluations were spread over the majority of the clinical specialties  
160 delineated by the Medical Board of Australia.<sup>8</sup> The majority were evaluations of models  
161 delivered by nurses and allied health practitioners. The review was limited to Australian  
162 evaluations published in peer-reviewed journals. There are likely a large number of evaluations  
163 that have been published as non-peer reviewed reports, such as evaluations of advanced  
164 musculoskeletal physiotherapists,<sup>15</sup> and urgent care centres in public hospitals.<sup>16</sup>

165 Evidence on the effects of health care delivery models generated in other countries can inform  
166 Australian health policy and practice. However, the review focussed on Australian evaluations  
167 because the local context is a more important determinant of the effect of a health care delivery  
168 model than of **the effect of** pharmaceuticals and other ‘simple’ health technologies.<sup>17, 18</sup> There  
169 are differences in local context between jurisdictions within Australia, but the commonality of  
170 providing health care within the Australian health system, with its unique organisational  
171 structure and funding mechanisms, increases the relevance of Australian evaluations of health  
172 care delivery models.

### 173 **Evidence-based Service Improvement**

174 As outlined by Scrivens,<sup>19</sup> health service planners and decision-makers are commonly faced  
175 with a range of *explicit standards* that are used to monitor existing services from institutions  
176 external to their organisations (e.g., the National Health Performance Framework,<sup>20</sup> Service  
177 Level Agreements between state & territory government departments and Local Hospital  
178 Networks and reports from clinical registries). Decision-makers also face external incentives  
179 and pressures from a range of ad hoc *expert judgements*, in the form of commentaries on  
180 performance. Examples of these include non-routine government department reports and

181 white-papers (e.g., the Atlas of Healthcare Variation<sup>21</sup> and CSIRO Future of Health<sup>22</sup>); reports  
182 by stakeholder and interest groups (e.g., Palliative Care Australia<sup>23</sup> or the Grattan Institute<sup>24</sup>);  
183 through to academic research (e.g., NHMRC funded evaluations of existing and emerging  
184 practices) and commercial developments (e.g., new communications and logistics  
185 technologies); and media investigations (e.g., newspaper articles on sentinel events). Such  
186 external evidence often drives internal self-assessment and shapes opinions on the actions  
187 required for improvement.

188 State and territory health departments support the development of ‘models of care’ in  
189 prioritised clinical areas, for example, the Agency for Clinical Innovation in NSW has  
190 developed a wide range of models of care.<sup>25</sup> These models of care outline best practice care,  
191 describing the services to be provided and the health care practitioners **needed** to provide the  
192 required services.<sup>26</sup> The re-organisation of health services to implement the developed models  
193 of care (i.e., the development of health care delivery models) is undertaken with Local Health  
194 Districts, who may need to develop localised business proposals to justify the resource  
195 implications associated with implementation.<sup>3</sup>

196 **Searles et al reviewed the use** of local level evaluations of healthcare in Australia and found  
197 inconsistency in the conduct and quality of local evaluations.<sup>27</sup> This confirmed findings from  
198 previous studies, such as experience at Monash Health that “evidence is not used systematically  
199 or proactively to drive decisions”.<sup>28</sup>

## 200 ***Local Level Evaluation Framework***

201 **Health service managers and leaders follow many heuristic processes to inform changes in**  
202 **practice, in the context of varying local resource and cultural constraints and preferences of**  
203 **local stakeholders.<sup>29</sup> Local health systems are complex, a response to which is an aim “to turn**  
204 **healthcare into a learning system, with participants attuned to systems features and with strong**

205 feedback loops to try to build momentum for change”.<sup>1</sup> Local level evaluation frameworks may  
206 support the move towards a learning health care system, providing a formal basis for the  
207 investigation of local health system features and the explicit and contestable evaluation of  
208 proposed options to improve local health services.

209 In their review, Searles et al outlined a framework for local level evaluation in the Australian  
210 health system, which was informed by a review of health technology assessment (HTA)  
211 frameworks, in consultation with senior Australian health service managers and clinicians.<sup>27</sup>  
212 The framework includes processes of evidence gathering and initial evaluations of new health  
213 technologies and models of care, leading to an implementation decision. Following  
214 implementation, Searles et al describe the need for ongoing monitoring and evaluation to  
215 improve, or optimise the implemented intervention, as well as to identify whether an  
216 intervention fails to provide value and is a candidate for disinvestment.

217 In their survey of representatives of 27 different health services, Searles reported that 81%  
218 identified a lack of evaluation staff and skills as a barrier to local evaluation.<sup>27</sup> To apply a local  
219 evaluation framework, capacity is required to identify and undertake initial evaluations to  
220 inform the design and implementation of new health care delivery models. This process  
221 requires the estimation of the value of new delivery models relative to existing delivery models  
222 for defined populations in local health services, combining evidence on the effectiveness of  
223 new delivery models with local health systems data and stakeholder engagement to design  
224 locally relevant evidence-informed delivery models.<sup>30</sup>

225 In Australia, such evaluations may be best undertaken at the Local Health Network or Primary  
226 Health Network level, but such institutions are unlikely to have sufficient capacity to design  
227 evidence-informed delivery models on a routine or regular basis.<sup>27, 28</sup> It may also be wasteful  
228 to duplicate all evaluation activities across different local health services. To address these

229 issues reviews of evidence on the effects of new delivery models could be undertaken by an  
230 external organisation and disseminated to local health services. Likewise, analysis plans for the  
231 synthesis of evidence on the effectiveness of new delivery models with local health systems  
232 data could be developed externally and disseminated.

233 The NHMRC accredited Advanced Health Research and Translation Centres (AHRTCs) and  
234 Centres for Innovation in Regional Health (CIRHs) and the umbrella Australian Health  
235 Research Alliance (AHRA), are well placed to co-ordinate the design of locally relevant  
236 evidence-informed health care delivery models. These Centres could facilitate linkages  
237 between local health services and local researchers to undertake local evaluations, whilst  
238 AHRA could facilitate the co-ordination of activities nationally to disseminate relevant  
239 resources across jurisdictions. Funding for local and national activities could be provided  
240 through the Medical Research Future Fund (MRFF), given the relevance of the proposed  
241 activities to MRFF priorities (e.g. Comparative Effectiveness Research).<sup>31</sup>

## 242 Conclusions

243 The most recent Council of Australian Governments (COAG) Heads of Agreement on public  
244 hospital funding and health reform expressly referred to the further development of nationally  
245 cohesive HTA.<sup>32</sup> Currently, the COAG Health Council Health Technology Reference Group  
246 provides evidence-based advice on emerging technologies, but this Group focuses on specific  
247 procedures (e.g., ablative techniques for the treatment of localised prostate cancer). There is no  
248 equivalent group focussing on health care delivery models, despite the abundant evidence base  
249 and the fact that the majority of government spending on health is used to employ health care  
250 practitioners,<sup>33</sup> whose value is greatly influenced by the health care delivery models within  
251 which care is delivered. Further development of nationally cohesive HTA should explore  
252 options for a co-ordinated system for the development and dissemination of resources to

253 support local evaluations by health services to assess the value of new health care delivery  
254 models, in local settings. The AHRTCs and CIRHs, under the umbrella of the AHRA may  
255 provide the infrastructure to support such a system.
